

**Multimodal Partial Volume Correction: application to [^{11}C]PIB PET/MRI
myelin imaging in multiple sclerosis**

Supplementary Material

ACCEPTED for PUBLICATION - JCBFM

Figure 1 - Graphical representation of wavelet decomposition when applied to a 3D volume as a MRI scan (second row) and PET image (third row).

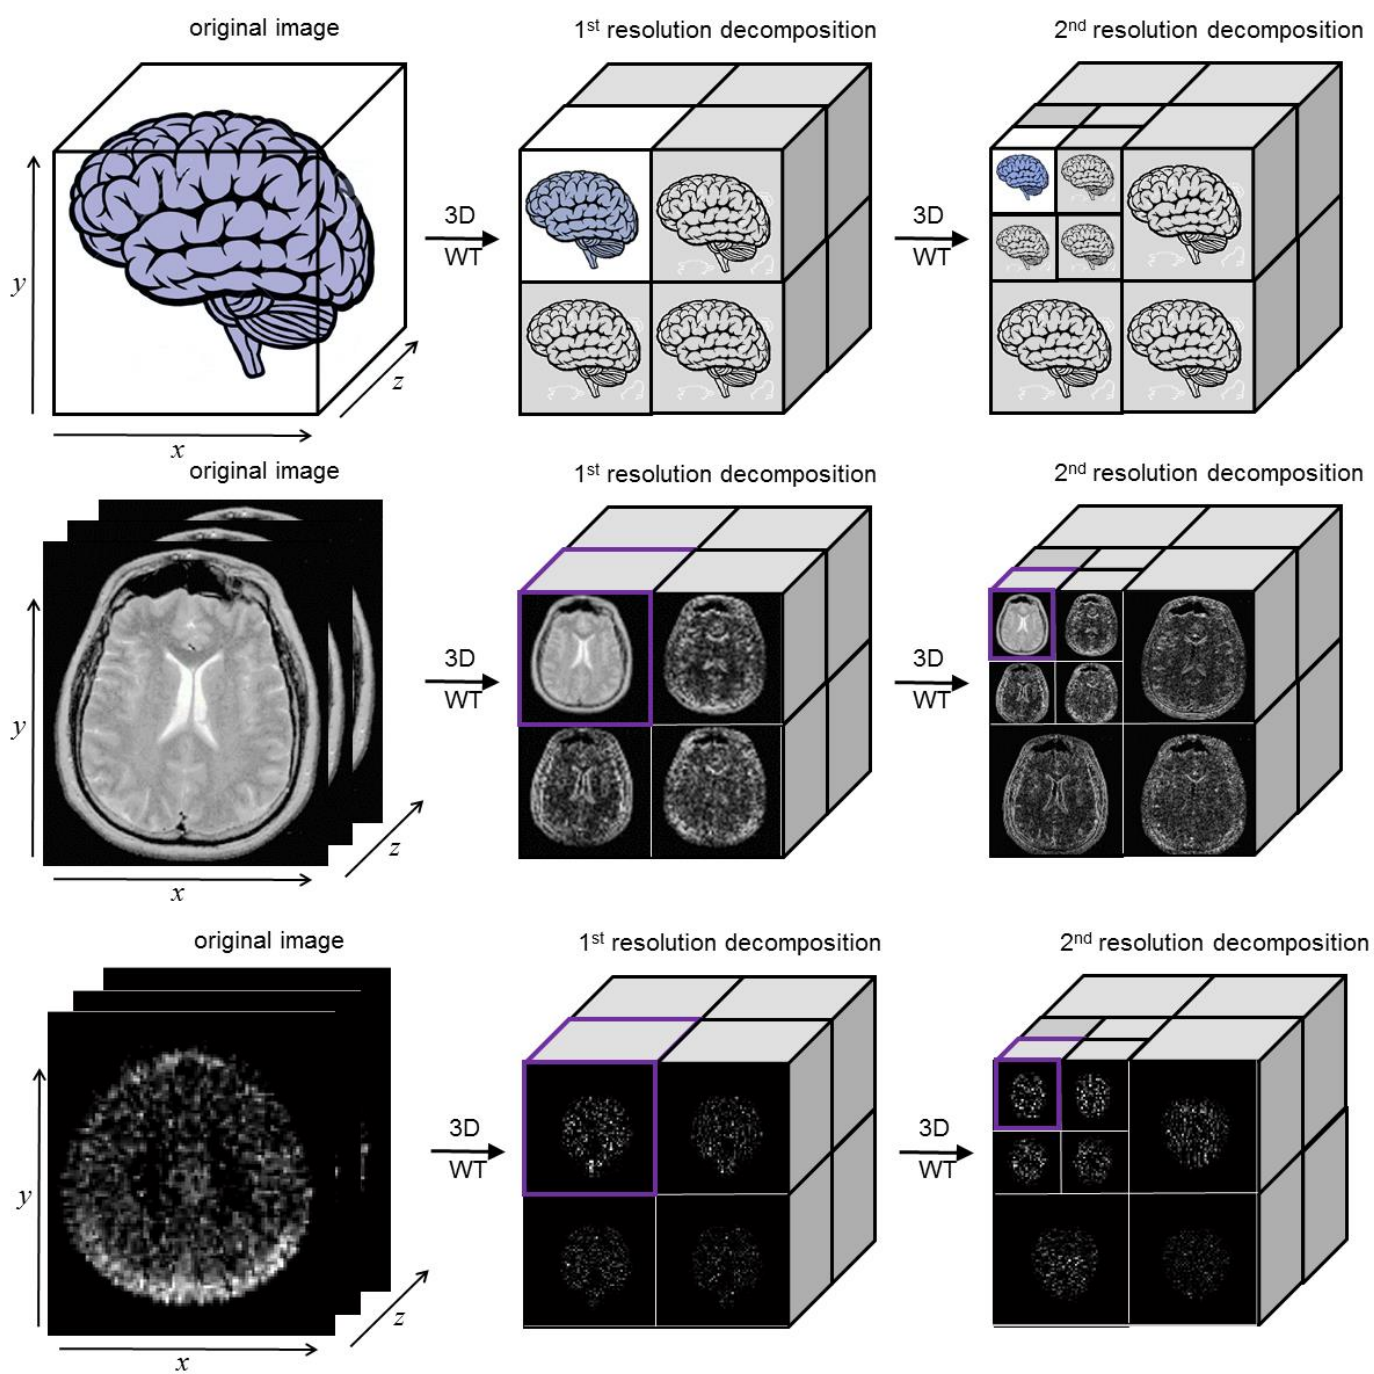

Figure 2 - Contrast local analyses. The mean and standard deviation of white matter (WM)/grey matter (GM) contrast values are reported for Scanner PET images and MM-RR PET images for different ROI sizes.

Figure 3 - Comparison of [^{11}C]PIB DVR lesion quantification between Scanner PET and MM-RR PET as function of the lesion volume. Each mark (white circle for Scanner PET and grey square for MM-RR PET) shows the average [^{11}C]PIB DVR for a given lesion and its volume. The two lines represent the regression model of the data (dashed line for Scanner PET and solid line for MM-RR PET)

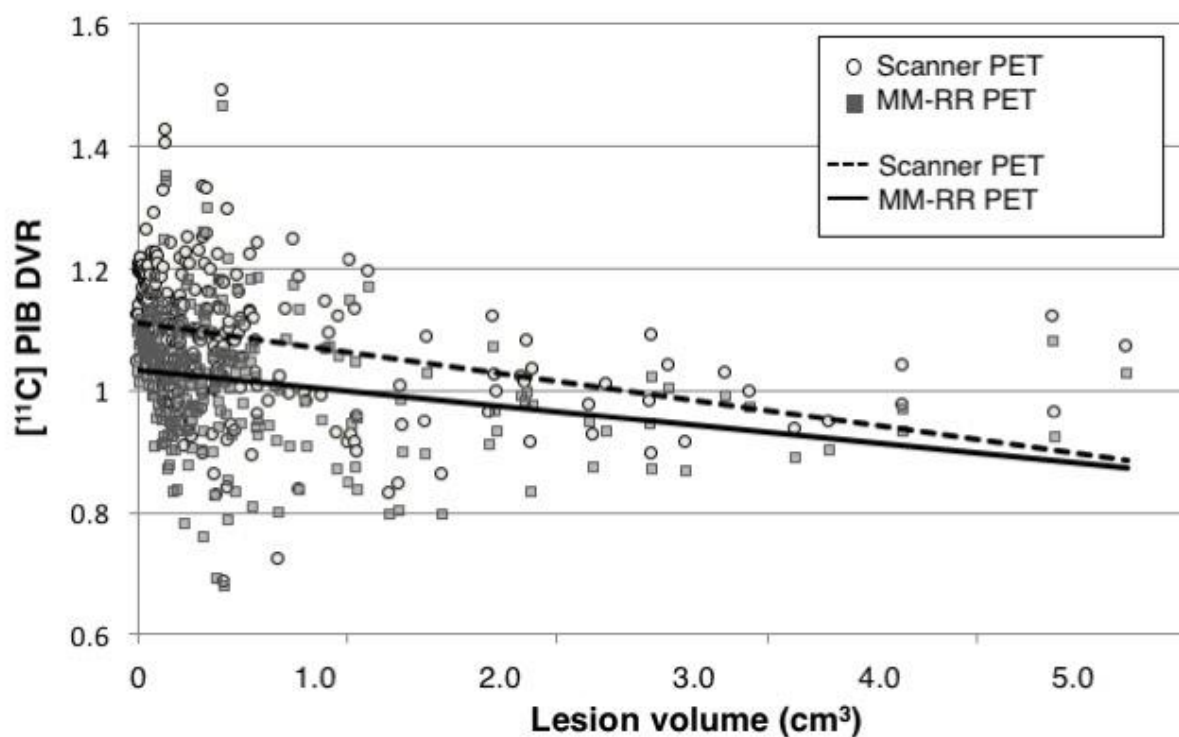

Figure 4 – Application of the MM-RR method to [^{18}F]FDOPA PET Imaging. The figure shows the axial view from a representative control subject of a [^{18}F]FDOPA PET/MR scan. Left column structural MRI image; central column Scanner PET; right column MM-RR PET. Colorbars for PET images represent dopamine synthesis capacity (K_i^{cer} 1/min).

Figure 5 – Effect of MRI-PET misalignment on MM-RR correction. PET colour bar indicates DVR estimates (unitless).

Figure 6– Example of Gadolinium enhanced lesion for a representative MS Patient. Upper panels show T1 images with Gd+ lesions highlighted in red circles, Lower panels report the Scanner and MM-RR.PET with Gd+ highlighted in white circles.
